Announcing **BOHNALITE**

36% Lighter than Aluminum
78% Lighter than Iron

Extreme lightness in metal! Here is Bohn's latest contribution to the aircraft industry.

Bohnalite X is the lightest metal on the market that is practical for aeronautical engine parts, hardware items, windings, etc. For this new alloy is 36% lighter than aluminum and 78% lighter than iron. Here is a weight saver in the full sense of the word.

Can be used for castings, forgings and extrusions.

Write today for complete information and physical properties.

Aluminum Division

BOHN ALUMINUM & BRASS CORP., DETROIT, MICHIGAN
New York Chicago Philadelphia Cleveland Pittsburgh

JUST as the Glenn L. Martin organization pioneered in the solution of mastery of the air, it is now pledged to pioneer in perfecting new contributions to the art of aeronautics.

BLAW-KNOX HANGARS

BLAW KNOX Galvanized STEEL HANGERS are the result of special and engineering research to determine the most economical type of hangar construction to fit all requirements of airport or landing field.

Over twenty years experience in the construction of Standard Steel Buildings has resulted in Hangars which are—

1. Made from stock units, easily erected, enlarged, changed in shape or moved as occasion requires.
2. Fireproof.
3. Weatheright and easily heated.
4. Provided with any type of swinging, sliding, or folding doors.
5. Low in first cost and extremely low in maintenance.

Send for fully descriptive literature

TRAVEL AIR *renews* BERRYLOID CONTRACT

TRAVELAIR "NEW" PHOTOGRAPHED IN THIS GROUP BY STANLEY PARKER AND BEAL.

January 25, 1929

Berry Brothers, Inc.,
Detroit, Mich.

Gentlemen:

We are indeed very glad to endorse your product for aviation use, as it has given us complete satisfaction during the few years of manufacture of Travel Air planes. We have placed your 1928 contract fulfilling that Berryloid is one of the best products on the market for aircraft use.

Assuring you of our appreciation of your co-operation throughout the past year and looking forward to the same pleasant business relation during 1929, we are

Very truly yours,

THE TRAVEL AIR MANUFACTURING COMPANY

R. W. Edwards
PRESIDENT ADJ.

WILBUR, KANS.

Many airplane manufacturers contract with Berry Brothers for their canvas building requirements. Travel Air has renewed its agreement for 1929, expressing complete satisfaction with quality of materials and the service rendered. Every Travel Air, beginning with number one, has been finished from spinner to rudder with Berryloid.

Thorough training is the background ▲▲▲

of every polished pilot

New Planes—Spartan Training planes powered only with nine-cylinder, radial, air-cooled motors, are used exclusively in the Spartan School of Aeronautics. Planes and motors are inspected regularly by Government-trained mechanics.

Army Instructions—The Spartan School instruction staff consists entirely of military men holding transport pilot (the highest grade) government licenses, chosen because of desirable Army background and ability to impart knowledge to others.

Accommodations—Students studied quarters fifty yards from the airport are attended by the Spartan School at cost. Paraded mess, reading room, showers and garage, meals at the airport dining room. An ideal arrangement for students.

A Great Airport—Tulsa's 400-acre municipal airport is the Spartan School training field. It has been laid out in accord with modern, airport requirements and is recognized as one of America's finest municipal airport projects.

Factory Facilities—Spartan School students have access to the Spartan factory for information of importance to the progress of their aerial flying. In the factory, students may study construction and airplane structure in its various stages.

Aviation Center—Four airports and a government national airport station are located here in Tulsa's important air installation center. Three passenger carrying lines, one using biplanes, two Fokkers and the air mail, operate from the Municipal Airport.

LABORATORY, TEST BLOCK AND FLIGHT

-TP- Aero Valve Spring Lubricant

For Valves, Springs,
and Valve Guides.
Keeps—Does not
burn or carbonize.
Sold 10¢ (5) per
oz. can.

-TP- Aero Rocker Arm Lubricant

A pure, paraffinic,
base, low-cold-set,
mineral oil.
Keeps free flowing
—will not carbonize.
Sold 50¢ for
1/2 qt. can.

BY every test -TP- Aero Motor Lubricating Oil plainly demonstrates its superiority. It represents a great stride ahead in the science of lubrication. -TP- eliminates many causes of engine trouble — reduces the risks of flying.

-TP- Aero Motor Lubricating Oils are new—the latest development in scientific lubrication. They have been tested and approved by leading manufacturers of airplane engines and by many leading pilots. They are straightening oils, not blended or compounded, produced from pure, paraffinic-base crude by a process for which patents are pending.

This process has marked advantages:

over other methods. It removes all the paraffinic wax, while preserving all the lubricating bodies in the crude. Elimination of the wax is responsible for its low cold test.

In terms of performance this means uniform viscosity at all working temperatures, minimum carbon deposit and ignition trouble from fouled spark plugs, easy cold starting, immediate oil pressure, perfect lubrication winter and summer, on the ground or at high altitudes—a maximum of safe flying hours.

A New-Day Plane with a Background and a Future

Surprising Wing Strength

This photograph of heavyweight men standing on the Barling NB3's patented wing gives some idea of the great strength engineered into the wing. Six well-matched men the total weight of the ship has been successfully applied to the wing—without any indication of weakness.

The New-Day Barling NB3 takes off from a background of established stability. Its manufacturers, the Nicholas Beazley Airplane Co., Inc., are not adventurers in the field of recreation. This firm, already America's foremost aviation supply house, enters the manufacturing division with experience—valuable in both the production and marketing of this New-Day Plane.

And the NB3 is not just another airplane. It is an entirely new conception of construction and performance—embodying the qualities that give popularity and stability.

Performance is phenomenal. Record after record has been shattered by the NB3—and inherent stability permits the novice to fly it with ease.

Amazingly low in price, this all-metal structured, three place, low-wing monoplane, completely equipped, is only \$3600—4½ way Marshall.

Successfully established dealers may still obtain franchises in a few desirable territories.

Vacuum Oil Company . . . presents

A new "double range" Mobiloil made especially for today's high-speed, heavy-duty aircraft engines

The Vacuum Oil Company celebrates a quarter century of leadership in the air with a new contribution to the science of aviation—Gargyle Mobiloil Aero H.

The rapid development of commercial aviation has placed an added burden upon lubrication. With characteristic foresight Mobiloil engineers have been working to perfect an oil especially adapted to the new requirements of today's high-speed, heavy-duty aircraft engines. Their efforts have met with remarkable success.

Mobiloil Aero H possesses certain definite advantages over other oils now in general use for airplane engines:

1. "Double range"—body and viscosity under severe heat and load conditions combined

with easy starting and exceptional fluidity at low temperatures.

2. Less carbon deposit.
3. Freedom from gumming—(in clean engine).
4. Low evaporation, low consumption.

These facts about the new Mobiloil Aero H are based upon conclusive tests conducted by leading aircraft engine builders in the United States and abroad.

The new Mobiloil "double range" Aero H is now on sale at, or continuously near, every airport in the country. Prove its performance in your own engine.

THANK YOU for watching AVIATION

There's No Excuse for Failure!

The mails must go—passengers must have safe, dependable transportation. That is why the Universal Aviation Corporation, operating fleets of passenger and mail planes between Chicago, Kansas City, St. Louis, Omaha, Indianapolis, Cleveland and Louisville, chose Stanolind Aviation Products to protect their great Wasp and Hornet engines against friction.

The determining factors resulting in this choice were: Quality of Oil and specialized Lubricating Service.

Stanolind Aviation Gasoline and Stanolind Aero Oils are the choice of an ever increasing number of pilots and air transport companies throughout the Middle West. The purity and uniformity of these aviation products have been proved over long periods of air mail flying and in the exacting requirements of air races. Never has an engine failure been traceable to their faulty operation.

Volume 61 Number 61

One National Show

ANATIONAL AERONAUTICAL EXHIBITION is a rather exhausting affair to the visitor and exhibitor alike, but to the latter it is also very expensive. Every aerodrome show, such as the one held recently in Detroit, attracts the industry close to a quarter of a million dollars. However, the effort and the cost are really well worth while, for the same results can not be accomplished as quickly, effectively, or as cheaply in any other way.

On the other hand, the benefits to the industry to be derived from national shows diminish rapidly in accordance with the number of shows held during the course of a year. That being so, it would not seem practical, nor probably to hold more than one national show a year, particularly now that the manufacturers are concentrating on yearly models. There can be only one "first showing" of a plane, and that should be at the one big national show which would be attended by the entire aeronautical class. And in addition, it is believed that the national show should not be held in the same city each year. Every big city should have a chance to hold the national show, if for no other reason than the stimulating of public interest in aeronautics in that particular section of the country.

Production and Progress

ONE OF the greatest problems now facing the aviation industry is that of suitable methods for manufacturing production. It is impossible to build good aircraft economically so that they may be readily serviced in the field, unless the manufacturer employs costly production jigs and special tools. At the same time it is apparent that since a manufacturer has thoroughly equipped his factory for the production of one model he will not welcome improvements in the plane which would necessitate making his expensive special equipment. Thus on based effort to build better planes inevitably acts as a bar to progress in the improvement of existing types.

It is evident that the aircraft industry needs production equipment, at the present stage of development, more than it needs aerodynamic engineers. Men who can design satisfactory production tools and jigs which will at the same time be adaptable to changes in the airplane and be adaptable to such changes at a low cost, are badly needed. Such engineers must be developed, for through their efforts alone our aircraft building be placed on a par with other great industrial efforts.

Illumination of Instruments

ASAVING of \$2.50 that eventually led to a repair bill of \$2,500 seems almost incredible. Yet it is wadded for by a private plane owner who has lost both business and pleasure.

When he bought his plane it was with the intention of using it only in day flying and always landing before dark. Consequently he could see no need of paying for radium or luminous dials on his instruments and thereby saved about \$2.50. All went well until he was overtaken by darkness much earlier than he expected, on his way home and where he thought he knew the country perfectly. Things look differently, however, in rapidly growing darkness and he became lost as his compass was not illuminated and he feebly made a forced landing that almost wiped out the plane.

As the result of cases of this kind certain makers now refuse to sell instruments without luminous dials. Even when bought for training planes to be used only over a local field, there is no exception that they may not at some time be transferred to another plane. They also recommend a rheostat in the lighting circuit of illuminated instrument boards so the pilot can adjust the illumination to suit his vision. With the light changes between daylight and dark, the eye does not always accommodate itself rapidly enough to maintain vision with only the luminous dials, and full illumination may be needed during the dusk or twilight period. As the darkness increases the illumination can be reduced and the luminous dials show plainly without aid from the lighting system.

Ford Motor Company

By JOHN T. NEVILL

PROBABLY no single event, except for the entry of the government into the air mail field, bore more significance to the country's aircraft industry up to 1928 than did Henry Ford's dignified notice published in the *Ford News*, Aug. 8, 1925, that his company had located into the airplane manufacturing business.

That information, coming to light in complete accord with the typical Ford equation, was interpreted by laymen over the nation to mean that perhaps "there was some thing in this aviation thing after all." The layman's thought was based upon his knowledge of Ford's business judgment and the proven ability of Mr. Ford not only to see a hidden market for a given product but to foresee the possibility of and create a market for that product.

And it may safely be stated that those already within America's aircraft industry, such as it was, at that time, welcomed the Ford Motor Company into their ranks, viewing the announcement as a sign to the nation's mind of a definite resolution of their dreams, if not as a definite turning point toward the financial health of the industry.

It would be an injustice to those pioneers in American aviation—the Curtiss company, the Wright company, the Packard company, and several others—even to surmise that they would have hesitated to stick at their pen and fight their way through to the bright air enjoyed today. Yet, that being as it may, there can be little doubt that the interest of the Ford Motor Company has encouraged other capital and greatly accelerated progress of the industry toward the happy condition existing at the present time.

A man of considerable aeronautical prominence, visiting Detroit not long ago remarked that "a seat for Ford Airport is a large part of an education in commercial aviation." That remark was well put. When a visitor sees first on Ford Airport today he sees one of the largest, most modern, and most completely equipped commercial airports in the United States—sit on property that less than five years ago was tree covered and unused. He sees more than 500 acres of level land, with runways 2800 ft. in one direction and 2400 ft. in another, a large part of which remains as concrete

Henry Ford, president of Ford Motor Company. Left: William B. May, then president of the Ford Motor Company, Detroit.

He sees a row of ultra-modern airport buildings, now recently completed, on the exterior side of the field, large as a football field, but dwarfed by the noticeable expense of the field. He views an up-to-the-minute airplane factory, where materials are brought in at one end and one of the world's fastest airplanes whirled out at the other.

Today's visitor to Ford Airport sees two large hangars, one of them being 125 ft. wide and 300 ft. long, containing a number of the world's best known history-making

airplanes. On the field is one of the most modern dirigible mooring masts in the country, towering 208 ft. into the air, yet representing virtually no hazard to one of the field. He sees airplanes taking off and landing almost hourly, operating on regular schedule with passengers, mail and express. He observes a splendid passenger terminal building, and to be one of the finest airport passenger stations in the United States, serving actual passengers such as the railway station serves the railroad traveler and the bus banger he expects a United States Government weather station, probing constantly into the status of the upper air, the highways over which the post's planes operate. He enters a radio building and hears other airports giving their weather reports and messages into beards. There he views a huge electric motor, transmitter, code analyzer and receivers of the radio beams, equipment having been proven capable of giving a properly equipped aircraft hundreds of miles distant, on a line-line to Ford Airport.

At night he witnesses a system of illumination second to none in the nation, guiding planes to the airport, showing them the exact boundaries of the field, and creating artificial daylight over the ground itself, that the aviator might bring his craft down in absolute safety.

Despite the few years of its existence Ford Airport has been the scene of a number of memorable milestones in aviation progress. Here it was, that Henry and Edsel Ford began America's first regular auto-company

AND AMERICAN

AERONAUTIC DEVELOPMENT

airplane mail and express line. Here was inaugurated the second successful domestic contract air mail route to go into operation. Here was created the first privately owned dirigible mooring mast in the United States. And here was demonstrated publicly that an airplane could be navigated from one point to another and almost point and return safely by the use of radio.

IN THE PART TWO (page 180) of a series of articles, a month's sort of way the Ford airplane picture as it is today. Meanwhile a question arises that, for purposes of the series of articles, might better be answered now. Just why and how did the Ford-aviation?

Henry Ford has given his son Edsel, full credit for being the first of the two to interest himself in commercial aviation. This probably is as it should be, since Edsel Ford was one of those "spontaneous" who contributed money to William Bushnell Stout when that versatile gentleman came to Detroit with what was then a vague scheme to build commercial airplanes.

However, to answer the question why and how did the Fords get into aviation it will be best to stick back a few years and introduce a small group of men who introduced aviation to Detroit.

As a matter of record Detroit's initial aviation activity was brought about by the same group credited with bringing the Packard Motor Car Company to Detroit.

It is altogether probable that very few members of the industry have ever stopped to consider the tremendously important part that the Ford Motor Company has played in the development of American aeronautics. And fewer still have stopped to realize that the Company's active interest dates as far back as the period of the World War. In a series of articles, of which this is the first, Mr. Nevill presents a most interesting detailed and graphic picture of Ford aviation progress from its beginning up to the present time.

Henry B. Joy, son of one of the men responsible for the Michigan Central Railroad, Fred M. Alger, son of General Russell A. Alger, Secretary of War during the Spanish-American War and a number of equally influential associates brought the Packard Motor Car Company to Detroit from Warren, Ohio in 1903, the same year the Wright brothers made the world's first airplane flight.

Henry B. Joy, a man who has a penchant for experimenting with new ideas, happened to be on an automobile tour, such as automobile tours were in those days when he heard that the Wrights had made their flight. He left the tour and hurried to Kitty Hawk. A short time later Mr. Joy became one of the few men having the distinction of having flown with one of the Wright brothers.

In 1903, Mr. Joy, the two Alger brothers, Fred M. and Russell, and a number of friends interested with them in the Packard Motor Car Company, attempted to persuade the Wrights to locate in Detroit. But they were unsuccessful. The Algers then purchased a Wright plane and took it to Detroit, giving that city its first view of an airplane.

A few months later, in 1911, the same group of men organized the Aero Club of Detroit, the first such club in the state of Michigan and an organization now long out of existence. The plane piloted by a man named Frank Coffey, was the first light plane to leave St. Clair,

A Ford Model A airplane, showing its high-wing configuration and open cockpit.

a flight regarded as extremely hazardous in those days. Fred Alger rode with Coffin on that occasion. Coffin and Russell Alger a few days later started from Gander's Point, on Lake St. Clair, where the Aero Club was located, and negotiated the first flight from the United States to Canada.

Only a few years later, after the start of the World War, Mr. Joy was one of the first men in Detroit to realize that aviation would be called upon to play a large part in that struggle. With this idea in mind he utilized the facilities of Packard Motor Car Company to construct an airplane engine experiments on which later formed a considerable part of the foundation of the famous Liberty motor. Many Detroiters still recall with a smile the novel way in which these early engines were tested. They were mounted upon a large Packard truck, with the propeller projecting over the truck's rear end. The engine of the truck was shut off and the airplane engine started. With only the propeller furnishing motive power, the truck was driven about the streets.

To the contrary, Mr. Joy, feeling that a flying field in the vicinity of Detroit should be provided, made a survey at his own expense and selected a site near Mount Clemens, Mich. He purchased the property and developed it into a flying field. In 1917, at the request of the Government, represented by Howard E. Coffin, now chairman of the Board of National Air Transport, Joy Field, by which name it was called, was enlarged and sold to the Government at cost. Joy Field became Selfridge Field in honor of Lieut. Thomas Selfridge, the first United States Army officer to die in an airplane crash.

Next came the Government's Aircraft Production Board, organized in Washington, to help out the Amer-

ican army into the air. Due to long neglect on the part of the Army officials the United States had very little to boast of in the line of aeronautics. The Board was created to direct American manufacturers in the production of aircraft material, and included in its membership such men as Howard E. Coffin, Maj. Gen. George O. Squier, head of the Signal Corps, U. S. Army, and Col. E. A. Dornier, head of the aircraft production division, U. S. Army. Mr. Coffin was chairman of the Board.

Since the United States had not yet produced any planes or engines that would be of any service at the front the situation facing the Aircraft Board was an extremely difficult one. This country had no samples of European planes or of European engines. Furthermore, we had no designs of these products by which to be guided. So a committee composed of two army engineers, two naval engineers, and two civilian engineers, met soon overseas to inspect the Allied craft and engines.

MANUFACTURE the Packard Company offered the Government design of the aircraft engine with which the company had been experimenting, but they were found too heavy for the horsepower developed. Col. J. G. Vincent, chief engineer of the Packard Company; Colonel Deeds, Col. Sidney D. Wollen, assistant to Colonel Deeds; and Col. E. J. Hall, of the Hall-Scott Motor Company of Berkeley, Calif., then evolved the design for an American airplane engine, the Liberty.

The Packard Motor Car Company constructed the first Liberty, an eight-cylinder engine, within six weeks. This engine successfully passed the government tests, and steps were taken to use every available facility to produce them in large quantities.

The next step was to assemble a large group of manu-

AVIATION

June 1, 1918

AVIATION

June 1, 1918

factors willing to curtail their respective commercial production and devote their plants to building airplanes and engines for Uncle Sam. The Liberty engine was but one of seven different types of engines to be produced; the manufacturers went through a process of design of several foreign engines. Engines to be built were the Liberty, the Hispano-Suiza, the Bugatti, the Hall-Scott, the Gnome rotary, the Le Rhone rotary, and the Curtiss. In short, the job at hand was to build 30,000 engines to cost \$14,000.

It was a large order and made considerably larger by the fact that the work had to be done with the utmost rush. To Harold H. Bennett, a Detroit attorney, serving his country in the Navy, fell the arduous duty of making charge of this engine production. Mr. Bennett later gave the task of Colonel in the Army; was the only naval officer assigned to the Army during the World War.

Colonel Bennett quickly assembled his organization. 33 engine building factories including

besides the Packard Motor Car Company, the Ford Motor Company, the General Motors Corporation, the Lincoln Motor Company, the Mack Motor Company, the Harrison Motor Car Company, the Franklin Motor Company, the Pierce-Arrow Motor Company, the Cadillac Motor Car Company, the Duesenberg Motor Corporation, the Curtiss Aeroplane Company, the Wright-Martin Aircraft Corporation, and many others.

Hardly had the engineering and testing work on the eight-cylinder Liberty been completed and serial production began, than word was received from the front that the eight-cylinder Liberty would be of no use there. It must be made into a 12-cylinder engine. Colonel Bennett's organization of engine builders received this message with a spirit to be highly commended and immediately began work on the larger engine.

The work done by these companies needs no dwelling here. It is suffice to say that before the Armistice, more than 30,000 of these seven types of engines had been produced the Liberty, as such type the Detroit arm concentration, totaled 14,000. Today nearly 11 years

later, many of them are still in use throughout the world. It might be pointed out, however, that since Detroit's position as the automobile center of the country has never been doubted, it can safely be taken for granted that the vast bulk of the aviation work done for the Government during the War, took place within the Detroit area.

After: Standing left to right: William H. Mayo, William H. Mayo, Albert Ford, Henry Ford and John E. D. Bennett standing before a Ford-built industrial structure.

Left: In left view of the Ford Works, Dearborn, Mich.

Colonel Bennett himself, in fact is authority for the statement that more than seventy-five per cent of all aviation material produced during the World War was built in and around Detroit.

The reader, perhaps, will begin to wonder just what most of the language paragraphs have to do with the question: Why and how did the Ford put into aviation? These paragraphs were written, first, to bring out the fact that Henry Ford was substantially engaged in the manufacture of war-time airplane engines prior to his entry as the commercial airplane field and, second, to disclose the front of credit of the "automobilists" of a certain group of engineers of Detroiters whose efforts have selected the last fact of Detroit, then of Henry Ford.

In the trying period shortly following the War, however, in aviation were called upon to re-sell the idea of aviation to the public—this time in a commercial sense. Aviation, however, not blessed with Government contracts could not very well exist. War-time jobs became "captive flies," flying here and there about the country, along on an uncertain living by "tomorrow's job hope" in a few advertisements persons. Some of the few auto clubs and flying schools existing before the war were re-organized, and many more such clubs began to spring up about the country.

One or two annual competitive air races were organized. The Palmetto of New York, started the Palmetto races in 1910. The Detroit group instrumental in organizing the National Aeronautical Association, under whose rules the air races were operated, succeeded in bringing the Palmetto races to Detroit in 1912.

Several years prior to this, however, the efforts of a race around whose activities the Ford airplane division was involved, came into reorganized being. That was the William H. Stout.

The crowd of the series of articles by Mr. Stout will appear in an early issue of AVIATION.—Ed.

The U. S. S. "Los Angeles" flying at the meeting meet at the Ford Airport, Dearborn, Mich.

THE FIFTH ANNUAL National Air Tour

John P. Wood, winner of the 1928 National Air Tour

WEARING a "brand new suit," i.e., a new committee, new manager, new referee, new rules, and several very interesting alterations in the rules, the Fifth Annual National Air Tour is scheduled to go forth from Ford Airport, Detroit, October 5, on a 10-day flight through Canada, the Northwest, East, Southeast, and Northwest, before returning to Detroit on October 21.

Although the start is still quite far in the future, plans for this year's event—regarded as one of America's premier non-aeronautical airpage events—already have gained sufficient impetus to mark it as a virtually certain success. Despite any implications that might have arisen out of the past tours, interest in the coming tour is well founded upon the contributions made by the by-gone events to the aviation industry.

At this writing, five proofs on the revised rules for the 1929 tour are off the press, and the complete regulations have been scheduled to be in the hands of prospective entrants within the next few days approximately four and one-half months prior to the tour start. Incidentally, the particular non-aeronautical of phoning the rules before the manufacturers and pilots so far in advance is in compliance with one of the major requests made by the pilot-entrants after last year's event.

Although as definite information is available at this time as to the number of manufacturers who have registered their intention of competing, Capt. Ray Collins of the United Trust Company, Detroit, who has been the tour referee during the past four years, will not yet have appointed to the new tour manager, states that the committee has seeking its first crew on that score. A tentative crew, approximately 4,000 in long and covering at least 28 cities in 30 states and two Canadian provinces, has been selected. This crew will take the participants from the Ford Airport to Whittier Airport at Whittier, Oct., probably the shortest jump of the tour. Then come Toronto, Ottawa, and Montreal, Canada and Portland, Me., followed by Boston, Mass., New York, N. Y., Philadelphia, Pa., Baltimore, Md., Richmond, Va., Charlotte, N. C., Greenville, S. C., Savannah, Ga., Jacksonville, Fla., Macon, and Atlanta, Ga.; Nashville, Tenn.; Louisville, Ky.; St. Louis and Kansas City, Mo.; Des Moines, Ia.; St. Paul, Minn.;

Winnipeg and Milwaukee, Wis.; Mobile and Chicago, Ill., and Indianapolis, Mich. The above route, Captain Collins said, is called "tentative," although with the possible addition of several cities, it is probably certain to be the route flown.

One of the most drastic changes in the rules and regulations this year is the fact that "fly-off maneuvers," or "offboard" places, have been barred from competition for the usual awards made to National Air Tour participants. These awards are the Edsel B. Ford Airplane Reliability Trophy and more than \$12,000 in cash prizes. "Offboard" places, however, have been limited to fly the tour as a sort of second award, taking off on hour or more behind the competing planes.

With reference to this change, Captain Collins thus says: "The primary purpose of the National Air Tour, as we see it, is to provide direct performance competition between airplane manufacturers and not to sell products, candy, radium, or the products of any industry other than that of aviation. Therefore we have decided that although the entry may be owned by either the manufacturer or an individual, it may bear no markings other than the name of the plane, the company manufacturing it, the name of the pilot, and, of course, the Department of Commerce license. 'Offboard' planes are being asked to join us on the tour, and we will be glad to have them, but they will be required to take off an hour or two behind us, and must carry all of their own expenses. Some special prizes will be competed for by the second competitors."

RELATIVE to expenses, it might be said here, that Manager Collins and the new tour committee have made some pleasing reductions in the appropriations asked from cities visited over the route. Cities where overnight stops are made this year will be asked to contribute \$1,000 in cash to provide gas and oil for competing planes, and to provide hotel accommodations for six pilots and one mechanic from each entry. The sum of \$500 is required of cities listed as midway stops.

The first alteration found in the rules for 1929 is an all-important one. It demands the acquisition of Approved Type Certificates issued by the United States Department of Commerce and flown with "letters

AVIATION

June 1, 1929

of merit" and other credentials that have sufficed in the past. Under the new order of things, the manufacturer must have the A.T.C. covering his entry no later than October 1—five days before the start. In 1930, it is contemplated to increase that time to 30 days in advance of the new start, Manager Collins stated.

The next major change we note in the rules concerns the method of scoring. Whereas, last year the rules employed the planes' maximum speed in the scoring formula, this presented an average speed on such individual fly of 80 per cent of the maximum, while giving credit for the maximum, the rules cover this year has increased the speed that must be averaged on each lap to 85 per cent of the maximum used in the formula. This revision was originally incorporated in the rules "to discourage racing and its attendant dangers," but last year the 80 per cent average "proved curiously too easy," Captain Collins noted, hence the increase.

Purported to be a head complete record by competing pilots last year that the important part played by the "stick," and "unstick" components of the scoring formula, proved entire in places not equipped with leaders, the rules committee has changed the formula to include only unstick the stick. Therefore, the correct formula will read as follows:

Maximum Department of Commerce model load multiplied by the maximum speed, divided by unstick-stick plus unstick multiplied by 30 divided by cubic inch piston displacement equals the figure of merit, or merit for one lap." or—

$$\frac{\text{Max. D. of C. Piston Load} \times \text{Max. Speed} \times .30}{\text{Unstick} + \text{Stick} + \text{Displacement}}$$

As was stated last year, the stick and unstick and speed tests will be made at Ford Airport previous to the tour, and the scores for each leg will be added up following completion of each leg.

Midnight of Thursday, September 5 has been set as the final date on which manufacturers may enter planes in the tour, and there will be no closing entries. This particular portion of rule No. 16, dealing with penalties for delayed entries, has been eliminated entirely.

Another change noted is in rule No. 26, which has to do with the provisions for delayed starts of the entire group from any of the several control points over the route. In the case of adverse weather, or any other reason that might be deemed sufficient to delay the start,

the manager and referee, under this year's rules shall decide the matter, without conferring with all of the pilots, as has been the case heretofore.

It is interesting to observe that the rules providing for use of a lower cubic inch displacement figure than that actually existing and that used in the scoring formula, provided in the past several years for awards of unstick-stick places on the condition their plans could attain given performances is left intact. This particular rule, No. 39, around was compiled last year from pilots of single engine craft on the basis that it gave the single-engine entrant an unfair advantage.

ONE extremely important addition to the rules is that no work will be permitted on competing planes during the night of the night stop. All test planes will be placed under guard immediately after fueling operations at the night stopping point. The entrant will be allowed two hours before starting the following morning in which to make any necessary mechanical adjustments or repairs. If the work should require a longer period than two hours one allowed prior to the scheduled time of departure, the entrant shall lose all points on the succeeding leg of the route.

A list of passengers will be required 30 days before the start of the tour, and any substitutions must be made five days prior to the start.

During previous years the National Air Tour has been sponsored by the Detroit Board of Commerce, and has been under the general management of a tour committee appointed by the Board. This year the tour was entered by Ford Motor Company, and has been taken over by a new committee, headed by William H. Mayo, chief engineer of the Ford organization. Although including several of the old committee members, the 1929 tour embraces many new names. Besides Mr. Mayo, the tour committee is as follows: Eugene W. Lewis, vice-chairman; William E. Messner, Col. Edward W. Rodenbacher, C. M. Mann, Frank W. Blair, Dwight Douglas, Charles T. Birch, Carl H. Keller, Ross Johnson, Thomas B. Cully, Warren Packard, Newton Skillman, Norman B. Conner, Edward S. Evans, and William F. V. Newcomb. Other names are to be added later, according to Captain Collins.

The tour rules committee is composed of Captain Collins, Capt. L. M. Wadsworth, Alfred V. Verville, Capt. Frank M. Hunsick, and Robert E. Lewis, of Troy, O.; Captain Hawks, holder of the present transcontinental non-stop flight record, will be tour referee.

A view of some of the airplanes in the Ford Reliability Tour, which was held from Sept. 28 to Oct. 3, 1928. Entrants were asked to land at 10:00 a.m.

THE PROBLEM OF *Rubbish* IN THE AIRPLANE FACTORY

By WILLIS PARKER

A FEW MONTHS AGO, I chance to meet and talk with a man who had the "conscience" for hauling away the waste products from a large airplane factory in one of the central states. He explained that he received no pay from the company for his work, but that he netted \$60 a week from his job which required but two days out of each week. For the privilege of hauling away the trash he paid the factory superintendent \$15 a week. Before proceeding with his load to the city dumps, this fellow explained that he sorted the trash and saved all of the scrap metal scraps, bits of copper and brass and other scraps of metal which he sold to junk dealers and averaged \$25 a week from the sales.

While we do not mean to intimate that there was anything wrong from this system, we do feel that there were wonderful possibilities for savings through co-operation between the trash hauler and employees of the airplane factory. If there was no such co-operation, the profit this man made from two days' work is sufficient to indicate that the airplane manufacturer should include in his organization a salvage department.

A western airplane manufacturing concern has its salvaging operations well organized and controlled—controlled in such a point that practically everything except the bark of an engine is saved.

From empty engine cases, discarded from the welding department, have been constructed vases and ashtrays. The waste cans are painted white and have the word "Trash" lettered on the side in red.

These cans are set up at convenient places in the factory so that the workers may deposit in the saving operations—drop waste materials into the waste cans and materials that might be used in other ways or which might be sold at a profit, into the salvage cans and assist the janitors accomplish their tasks with less effort.

It is a rule, in the plant, that the floors must be kept clean and free from scraps of materials because heaps of scraps scattered here and there not only are unsightly but presents a hazard to life and property. But it isn't advisable to permit the janitor to sweep continuously around the plant during the day time because it interferes somewhat with the workers.

The metal workers take a few minutes out at intervals during the day to sweep up the litter under their benches and machines and deposit it in cans provided for the purpose. The sheet metal workers drop their waste scraps of material into cans. Then the cans are removed

every night and dumped according to the contents of a label.

The removal is accomplished by litter carriers working on trolley lines—the overhead trolley need to carry various sub-companies of aircraft from one place to another in the factory and to the smaller factory units located at a distance from the main plant.

Special litter carriers have been constructed from empty 30 gal. oil drums—making salvaging operation. The cans are laid on their sides and a portion of the side cut out. Then they are swung by rods at the ends, and put off motor, to flanged wheels that operate on the overhead track. To prevent premature dumping, a linked, or ratcheted, strap of iron is fastened to one end of the drum and leads over an upright rod. When it is desired to dump the contents of the litter carrier, as it is called, the strap is lifted and the drum rolls over.

The overhead trucks run into every department of the plant, making it possible to dump the trash and salvage into the litter carriers without having to carry them more than a few feet.

Instead of the plant are three trunks drawn up in a row. One of them is to receive glass trash, another metal scrap, and a third wood scrap. The litter carriers are dumped into these trunks. When filled are loaded off—the trash to the dump, the wood scrap to the boiler room or to the lumber pile, from whence it is sold as kindling wood at \$3.50 a ton F.O.B. the pile. The metal scrap is collected near the railroad spur and when sufficient has accumulated it is loaded onto cars and sold to junk dealers at the market price.

Iron and steel shavings have not been profitable to save, according to the factory and ground equipment, because of their bulk, so they have, for the most part, been considered as glass trash and so disposed.

There is a possibility of considerable loss in the welding department in the discarding of short lengths of welding metal. In this plant, all lengths above 4 inches are sized and welded together to make long strips which are easy to handle in the welding process.

Salvaging operations even extend to the lathe activities inasmuch as efforts are made to prevent waste of metal and scrapped materials. The large first old boxes usually contain materials in large quantities. When a large batch of discards is opened to treat a small scratch or cut, it will deteriorate within a short time. Hence large cuts are being replaced by several small cuts and a saving results.

HIGH TEMPERATURE *Liquid Cooling*

The Delt General with Frank after showing one of cooling. Mr. Frank is standing in front of the plane.

THE EVOLUTION of aircraft engines to their present state has been through a long series of developments to reduce their weight and increase their efficiency with ever greater reliability. Each power output needed from the engine means an equal reduction in the total weight of the airplane which increases the aerial load. It is exactly the same reason. Use any means whereby the efficiency of an aircraft engine is increased by obtaining more power output from an engine of the same weight with the same amount of power, increases the fuel efficiency of the airplane.

The gradual reduction in weight of an engine has been accomplished by the use of stronger and lighter alloys in the non-critical parts and reducing their size to the minimum allowable for strength and durability to insure safe operation through severe design to show by the results of development and endurance tests.

The increase in efficiency has been slowly brought to its present state by improvements and advances in the operation of an engine such as developments and improvements in carburetors and intercooler, ignition systems and spark plugs, the use of higher compression ratios and superchargers and other means to increase its motion. Another method whereby the efficiency of an internal combustion engine is increased is by operating it at a higher temperature.

The water cooled type of aircraft engine, however, as the name implies, always been cooled by water. The cooling being accomplished by circulating the water

through a jacket about the cylinders and then cooling the water by means of a radiator through which a blast of air is passed at high velocity. Now, as everyone knows, water boils at 212 deg. F.—a fact which definitely sets a maximum operating temperature. A satisfactory temperature for

engine operation is usually considered as 180 deg. F. This allows a workable margin before the boiling point of the water. However, 180 deg. F. is much lower than the temperatures desired to obtain the greatest efficiency. Internal combustion engine engineers have been striving to find a satisfactory liquid which had a much higher boiling point than water to replace water as a cooling medium and permit the engine to operate at a higher temperature. Many different liquids such as mineral oil, kerosene, salt solutions, glycerine and other compounds have been tried but all have failed. Some are highly inflammable, some corrode the inside of the metal, and deteriorate the rubber hose in the cooling system. Other liquids in addition to the disadvantages mentioned, have a very low specific heat, which is the ability to take the heat from the cylinder and give it up again in the radiator. In fact, every one previously tried has had some very serious disadvantages which prohibited its use.

The engineers on the Power Plant Branch of the National Advisory C. S. Army, Air Corps have recently developed in the laboratory at Wright Field an almost ideal system for cooling the water cooled type of engine. This development has been the result of a number of

By GERHARD W. FRANK
Associate Mechanical Engineer,
Motor Division,
U. S. Army Air Corps, Wright Field

years of intensive research which has culminated in the successful operation of the system.

The liquid used in the newly developed system is ethylene-glycol. This liquid has a boiling point of 388 deg. F. in the pure state and has all of the properties required of a cooling liquid, which are relatively high specific heat, excellent wetting qualities and is non-toxic to metals. Also it is manufactured commercially and is comparatively cheap. Ethylene-glycol is the simplest of the polyethylene alcohols and is known chemically by the following symbol, $C_2H_4(OH)_2$. It is a clear colorless, odorless liquid and has a slightly sweetish taste. It is being used extensively by the auto motive industry as an anti-freeze. Since it has been known for fifty years it is not a newly discovered liquid, but its use in connection with high temperature cooling is a new development.

Since ethylene-glycol has a boiling point of 388 deg. F. it permits operating the water cooled type of engine at a higher temperature than ever before possible. The temperature limit most suitable at which to operate the engine is 300 deg. F. This temperature gives an ample size margin below the boiling point of the liquid. Also it eliminates the possibility of the formation of so-called vapor pockets in the cooling system which produce local areas of extremely high temperatures in the engine.

When operating an aircraft engine at a cooling liquid cooled temperature of 300 deg. F. it has been found that several highly desirable advantages are gained:

1. The amount of cooling area, or size of radiator necessary is greatly reduced.
2. A reduced amount of liquid is required in the cooling system.
3. A considerable reduction in weight of the installed power plant due to the reduction in size of the radiator and the lesser amount of cooling liquid required.
4. The parasite resistance of the airplane is reduced due to the reduction in size of the radiator.
5. It also permits the engine, supercharger, supercharger walls and cylinder barrels to operate at temperatures comparable to those in an air cooled engine with the added advantage of uniform cooling.

The radiator required to cool an aircraft engine when using ethylene-glycol as a cooling liquid and operating at the high temperature is approximately one-fourth the size of the radiator required to cool the same engine producing the same horsepower as when using water as a cooling liquid and operating at the normal temperature. The normal operating temperature of the water cooled engine is 180 deg. F. while with the new system the ethylene-glycol is operated at 300 deg. F.

The great reduction in radiator size is the result of operating the liquid at the high temperature which permits more efficient cooling in the radiator, due to the much greater temperature difference between the radiator and the cooling air. In the case of the ordinary water cooled system operating at 180 deg. F. with 60 deg. F. air temperature the difference is 120 deg. F. With the new system operating at 300 deg. F., and the same air temperature, the difference is 240 deg. F. or twice as much. Both benefits are realized. In the case of the present test it is pulled up by the liquid from the engine and only 25 per cent of the radiating area is required to cool the engine operating at the high temperature.

As previously stated the amount of liquid required is less than that in a water cooled system. This is due

to the reduced capacity of the radiator and the shorter length of connecting pipes required. In the modern piston airplane the cooling system has a capacity of 145 gal. of water. With the high temperature system this is reduced to 85 gal. which is a reduction of 5 gal. or 40 per cent.

The resulting reduction in size of the radiator and capacity of cooling system gives a considerable saving in weight. In an actual installation of this system the air-

Standard Curtiss P-3 B with water-cooled engine

plane weighs 3.5 per cent. less than when equipped with a water cooled system.

The resulting reduction in size of the radiator has the most important advantage of decreasing the parasite resistance of an airplane which permits an increase in speed, with exactly the same amount of horsepower. Normally the radiator offers approximately 15 per cent of the total parasite resistance of a piston type of airplane. Reducing the frontal area of the radiator 75 per cent. reduces the total parasite resistance of the airplane by about 12 per cent. The foregoing applied to airplanes equipped with the conventional type of radiator.

In the cooling system required for using ethylene-glycol as the cooling liquid and to operate at high temperatures very little change is required in certain types of ordinary water cooled aircraft engines. The changes necessary are few and should not increase the cost of the engine. The ethylene-glycol does not attack the metals in the engine and, therefore, no special provisions need be made for this purpose.

The operation of an airplane engine at 300 deg. F. is novel. There was practically no increase in wear or deterioration of the engine parts detected after a fifty-hour endurance test at the high temperature than when using water and operating at a temperature of 180 deg. F.

The Curtiss P-3 B piston type of airplane, illustrated, is an example of an application of high temperature cooling with a reduced conventional radiator horsepower type of radiator. A view of the same type of airplane equipped with the ethylene-glycol water cooling system is also given for comparison of the relative frontal areas and diameters of nose.

The Curtiss P-3 B airplane equipped with high temperature cooling in a Curtiss D-13-B engine has been given extensive flight tests. The greater part of the test it has been flown at full power engine operation at 2,300 r.p.m. The engine operation and cooling have been excellent and there has not been the slightest evidence of any trouble or disadvantage. The maneuverability of the airplane has been excellent as attested by all pilots who have flown it. The rate of climb has been increased and the airplane dives at a greatly increased speed.

June 1, 1939

June 1, 1939

THE FIRST NATIONAL Airport Conference

By CHARLES H. GALE

THIS AIRPORT BUSINESS is not as simple as it looks. Its deep and far-reaching ramifications are becoming more and more apparent and in time it may prove closer than the rain when a doctoring himself directly to airport design, construction and operation. So impressed have these men become with the extent of the job at hand that a walled forest to the many problems, common to a liquid method of attack. At least, about 200 directly concerned at the airport situation convened experienced and opinion at a convention at Cleveland, O. May 15, 16 and 17, under the auspices of the Airport Section, Aeronautical Chamber of Commerce.

Those experts know what they want and are not so to get it. The main problem is how to get these results they want and that is where the mutual exchange of ideas came in. Fully convinced that the airport as the contact point between air and land transport is the right hand man of general aviation security, they are determined that the country shall have the best possible in this line. This attitude was responsible for the earnestness which characterized the convention sessions.

Procedure has little to offer by way of guidance. It is a new field, the matter of providing adequate facilities for the proper conducting of air and land transport in the present and future. It becomes necessary to draw on the experience of other industries, the main one being taken from the history of the railroads. Lessons learned by these agencies in early experiments are used for the airport men.

The convention adopted an unanimous establishing fundamental policies, but there was one outstanding point on which there was unanimous agreement without formal action. That was that every effort possible will be made to look into the future and not to let the short-sighted errors in current development of other forms of transportation will not be repeated in aviation. That is the main achievement they seek.

Every section of the country and the Canadian government were represented. This meant that a wide variety of problems related to land conditions were represented, and as was to be expected, solutions deferred. All of which served to emphasize the complexity of the airport situation and the value of interchange of ideas. Every prominent phase of the airport was covered in the papers read and the informal interchange of questions which followed every session gave further opportunities.

What is to be the ratio between cost and weight of aircraft in the coming years and the size of the airports and length of runways required to accommodate them is a question which is causing considerable speculation. Genie

Hadden, civil engineer of New York, N. Y., discussed this in the first session.

The obvious most efficient ratio between the size of aircraft and the size of the airport runways, of course, the most economical point of operation. What this point is, is still a mystery. A counterpoint is to the railroad field where the 10 ft. gap probably would be the most economical and practical rather than the adopted standard gauge. In this connection Mr. Hadden explained his "Tricore" method of getting the greatest possible use out of the area available. This consists of three sets driven about an cylindrical triangle as a base. His theory is that, where there are any structures in the run or shape of the airport area, that largest number and the longest runways are provided by the equilateral triangle or the Tricore design.

Two fundamental points of expert soil analysis in coping with the drainage problem was brought out in an interesting paper by Wendell P. Miller, drainage engineer. Without a complete mechanical and chemical analysis it would be impossible to make an intelligent guess as to the drainage requirements he said and yet the vast majority of drainage systems are being installed merely by guess work. Analysis also helps solve the frost problem, he declared.

Photomontage in airport construction in general was urged also for the buildings thereon in a paper read by P. H. Forskell, manager of the Technical Service, American Institute of Steel Construction. Naturally enough, he emphasized the advantages of steel and explained its characteristics under various conditions. Steel was readily adaptable, he declared, to requirements and additions to meet changing conditions which progress may demand.

The same spirit of brightness is being urged in all another manner, that of the architectural aspect of construction. Why not have the airport and its buildings be things of beauty as well as utility? This proposition was championed by Francis Smith of the School of Architecture, Columbia University. The architectural aspect of airport should be taken into serious consideration by the designers, he said.

Separation of the various activities at the airport was declared by George M. Lord, Western Air Express, to be a very desirable measure. He was the first speaker at the morning session May 16, there being no evening session on the first day of the convention. General agreement to this view was registered by the convention. This would mean segregation as far as possible of the operations of transport planes, student machines, ordinary

planes, etc. Mr. Lord recommended placing transport operations on one side of the airport, taxi companies on the contractors and military and student work on the opposite side.

Close cooperation between the airport officials and the transport operators was one of his main points. The airport is addressed to being provided with all the apparatus of a modern air harbor, should take into consideration the maintenance and operation of the transport schedules and should see to it that the transport planes are given preference in arrivals and departures.

TRAVELER'S PREFERENCE runway seems to be in the ascendant. While there still are many leaders definitely committed to the all-weather test airport as the ideal, it appears that there is a growing trend toward the adoption of surfaced landing strips or runways as a solution to the seasonal and, frost, dust and foggy conditions. These difficulties are experienced particularly in the northern part of the country.

The cause of the trouble and hard surfaced runway was voiced by three speakers. W. E. Rosenberger, traffic engineer of the *Aviation Association*; George E. Macdonald, engineering manager, The *Barrett Company*; and E. R. Smith of the *Highways and Municipal Bureau*, Portland Cement Association. Mr. Rosenberger recommended that the *Aeronautics Branch* adopt a shorter runway length for a prepared runway on account of the greater runway clearance.

The speaker turned toward the lighter types of surfacing and described the so-called progressive type of development. This is the method of a light initial treatment which may be added to in succeeding periods, gradually building up a thick surface. This has the advantage of being economical and of providing something which will meet the unusual difficulties with the lowest possible investment. He favored two parallel runways each 25 or 30 ft. wide as opposed to the single runway of a 100 to 150 ft. width.

Taxiways and penetration measures surfaces also serve to meet seasonal water, frost and dust problems at comparatively low expense according to Mr. Martin. Once again as in Mr. Rosenberger's paper it was stressed that providing for the landing class of heavy planes on the airport surface must be provided and the known dirtiest area must be provided for available traffic with heavy, dense spots. It was agreed that while the traffic is still comparatively light in this respect, the lighter types of construction are satisfactory for the present.

Strategic construction in the form of gravel runways was the theme of Mr. Smith's paper. He pointed to installations at the Ford Airport and the Littora Airport near Rome, as examples of this method. He claimed that besides adequately caring for aircraft traffic, the present construction, applied to buildings as well as to runways, has a valuable psychological effect on the public.

WEATHER SERVICE PRACTICES are being developed rapidly and the work of the Department of Agriculture Weather Bureau was described by W. B. Greer, senior meteorologist of the Bureau. The stations of the Bureau are being installed along the runways as such runways are being extended in respect to the emergency wide system primarily, although local aids are available also. Airport aid on the runways but during weather service are being urged to install their own equipment of the type developed by the Bureau.

"What more rational than that successful attempts will eventually be made to alter the weather itself, to use an axiom at least of baffling the fog and low clouds, causing the troublesome squalls to follow airways remote from the main airways and possibly setting up zones in which only mid trails shall blow?" asked Mr. Greer.

Capt. F. C. Hingeburg, chief of the Aeronautics Division of the *Aeronautics Branch*, discussed matters of airport and plane lighting equipment, radio and weather aids and inter-field communication in a very interesting paper.

William B. Stout, speaking at the first annual dinner, May 16, announced he expects to see 100,000 privately owned planes within three years. Special government need be made for the operators of the "average" type who has not the advantages of the extensive training professional pilots receive. He prophesied, also, that extremely radical changes in aircraft design are due within a few years.

Private speed advertising becomes more in for considerable criticism. Representatives of light manufacturing companies and the Government agreed that the practice is becoming more and more of a detriment to night flying and opinion was strong that such restrictions should be discouraged. One delegate assumed that with the increasing number of private and official business, the lights have become very poor advertising mediums.

If any of those at the conference had failed to comprehend the increasing complexity of the legal aspect of airport establishment and operation, they were forcibly reminded of the fact by the excellent paper read by Prof. J. J. Freeman of the School of Law, New York University, at the afternoon session. Mr. J. P. Stout forbade an analysis of the many points developed by Mr. Freeman, but it is important to note that the volume of product in aviation law is making large proportions.

THE question of municipal liability for negligent operation of an airport seems to hinge upon whether or not the airport is being operated in a governmental or private capacity, or if a substantial revenue is being derived. In case of the latter two, liability hangs according to the status of individual states. New state legislation is required to disprove the contention.

On the other hand, according to Mr. Freeman, there is no such distinction in the matter of constituting a nuisance—that is, assigning low flying, confined noise and such disturbances—in liable irrespective of the nature of the facility involved or the capacity in which the city is acting. Here the legislature cannot release this situation, he declared.

Federal and state aids to municipal airport progress, are expected by Mr. Freeman to increase and be legitimated on an even smaller basis than the aids to highways. Some of these aids are exempting municipal airports from taxation by the state and the permission for joint municipal airport projects. Both of these are provided by legislation in various states. Such aids follow the old conception of the highways being the king's highways, in the eyes of the law.

Recent operations of airport and intermediate landing field lights by the pilot of a plane in the air was demonstrated by L. C. Simpson of the *Westinghouse Electric & Manufacturing Company*. The conference adjourned to meet time in May next year at Baltimore. The general feeling was that considerable progress had been gained in the cause of *Aeronautics* and that new or strengthened conceptions of the development projects will reflect infinitely the value of the convention.

THE Cunningham-Hall PT-6 CABIN BIPLANE

ONE OF the interesting new designs exhibited at the recent All-American Aircraft Show and indicating the tendency toward the use of metals in aircraft structures is the PT-6 cabin biplane now under construction by the Cunningham-Hall Aircraft Corporation, Rochester, N. Y. This plane has a conventional welded steel tube fuselage and a conventional steel wing structure. It has a capacity of six persons and is powered with the 76 Wright "New Wheland" engine which develops 300 hp. The PT-6 has a wing span of 44 ft. 8 in. and overall length of 29 ft. 8 in. and overall height of 9 ft. 11 in. The gross weight of the plane empty is 2,475 lb. The gross weight of the plane is 4,200 lb. and the payload 1,000 lb. In use, the plane attains a high speed of 140 m.p.h. and climbed at the rate of 1,000 ft. per min. with positive and 550 ft. of payload. The cruising speed is 118 m.p.h. and the landing speed is 45 m.p.h.

The all-metal wing structure consists essentially of duralumin ribs of the Warren truss type and chrome molybdenum steel tube longitudinal ribs. Tubing of 1 in. O.D. and 0.035 in. wall, heat-treated, is employed in the ribs, which are riveted with a special type of joint. These ribs have sustained more than 1,100 lb. in stress tests. Upper wing beams are of the three type consisting of upper and lower longitudinal ribs of 1 1/2 in. O.D., 0.046 in. wall and chrome molybdenum steel tubes heat-treated to more than 125,000 lb. per sq. in. tensile strength. The upper longitudinal ribs are reinforced for a considerable distance at the center.

ride spaces being employed to increase rudder shear and bearing strength. This type of construction insures a very rigid beam and prevents all repairs with any delay. Construction struts are made of $\frac{1}{2}$ in. CLD 0087 in wall duralumin tube Warren truss. Hinges are located at compression strut points and transfer forces down to the beam truss. The leading edge and aftmost hinge beams are heat-treated duralumin sheet. Lower wing ribs are of the same design and material as the upper ribs; the latter in the lower wings being

Left-Kaplan mounting and compressor duct. Right-4th rib struts showing internal bracing

large diameter chrome molybdenum steel tubes heat-treated and the compressor follows that of the upper.

Chrome molybdenum steel tubing is used throughout the primary structure of the engine. To facilitate protection, the bearings are locally sprayed by means of special dust at the joints, thereby avoiding the usual curved lower joints of the sliding members. The tubes are reinforced by corrugated duralumin sheet heat-treated, 0.016 in. thick. This corrugated sheeting adds considerable strength, breaks cracks and, furthermore, provides an excellent wall for oxidation and soundproofing purposes. Between wall is used in the work for oxidation against temperature and sound. Control surfaces have all metal structures ribs being made of W D 3025 carbon steel tube and other sections of the same specification and of chrome molybdenum steel tube and sheet. A conventional type of landing gear is employed and has been designed to avoid unnecessary external and secondary members. Axes are made of 34 in. x 0.120 in. wall chrome molybdenum steel tube heat-treated to 200,000 lb. per sq. in., tensile strength. Aural struts provide the shock absorbing medium. These are 3/8 in. x 3/8 in. pull tubes with solid steel eye bolts, pins and bogged ball bolts are used throughout the control system. Aural steel cables and turnbuckles are also employed. Cables run through individual aluminum tubes in the tubes with allowing all possibility of fouling. Brake pedals supporting brackets and fittings are high strength aluminum alloy forgings. Bolts and pins subject to wear have been chrome-plated.

The primary cabin accommodates four persons. The forward compartment accommodates the pilot and one other person. This compartment is separate from the main cabin which is accessible by means of an inter-compartment door. On either side of the pilot's compartment is a door so that entry and exit may be made

from either side without going through the main cabin. The pilot's seat is adjustable enabling the pilot to suit the seat position as to quickly change his position in flight. The second seat in the forward compartment is folding and drops down below the floor when not in use. The arrangement of windows in the cabin and in the panels of the two doors afford the pilot exceptional vision. The seats in the forward compartment are made of sheet and tube duralumin, and are equipped with seat and back cushions. Solid control is standard equipment. A dual set of controls, easily installed or removed, is provided for use of a relief pilot or for instruction purposes. The instrument panel is equipped with a complete set of flying and engine instruments, and is lighted by two sets of lights, one indirect and the other direct. A large baggage or merchandise compartment is located in the fuselage to the rear of the main cabin. The Cessna-Hall Aircraft Corporation as a business

organization is a new company, but actually it has a long experience in the aeronautical and automotive fields. The corporation is a combination of two groups. In the first group are men who have been actively engaged in the design, manufacture and operation of airplanes for many years. Randolph F. Hall, chief engineer, has been an aeronautical engineering work during the past fourteen years.

Through an arrangement between the Cessna-Hall Aircraft Corporation and the James Cunningham, Son & Co., the extensive plant facilities and the assistance and cooperation of the extensive experts and craftsmen of the latter are made available to the airplane corporation.

The specifications as furnished by the manufacturer are as follows:

Length	29 ft 4 in.
Wing span	41 ft 5 in.
Height	9 ft 11 in.
Wing area	370 sq. ft.
Weight empty	2,475 lb.
Pay load	1,000 lb.
Gross weight loaded	4,300 lb.
Wing loading	11.7 lb. per sq. ft.
Power loading	13.1 lb. per hp.
High speed	148 m.p.h.
Cruising speed	118 m.p.h.
Landing speed	45 m.p.h.

Bellanca and Bernard Awaiting Atlantic Calm

OLD ORCHARD (Me.)—As Atlantic gales press to start, the Bellanca and Bernard are held fast today for flights across the Atlantic as soon as word is received that the coast weather is fitting. The find in the fly school was made by Bellanca, "Scout Plane," in which Roger G. Williams and Lewis A. Mayne hope to fly to Rome, while the second is the Hyman-Spann-powered Bernard monoplane, to be flown by the Frenchmen, Jean Alouet, Rene Le Petit, and Antonio Lavi, in an attempt to span the distance between this country and Paris, France.

Trials for these flights were actually made at Roosevelt Field, L. I., there everything in readiness, the machines were placed in the true-Adventer take-off point to await good weather. But for the time being, the weather is not so good, and the men have had to wait with Dr. James M. Knudsen, of the New York Weather Bureau, hoping to receive the word which will be a signal for the start.

La Salle Leaves Plane Factory

POURCE (Ila.)—The La Salle Aircraft Corporation, a \$50,000 concern, has leased a factory at 111 Single Street for production of its light weight two-place plane which is to be put on the market soon at \$2,995. Plans of the firm, which is headed by J. C. Pong, is a one plane per week schedule. A 60 hp. LeRhain engine will power the craft, which at 21 ft. 6 in. in overall length, 7 ft. 5 in. in height, and 32 ft. in span according to measurements.

R. B. Reichen (left) and the other (right) standing beside Ryan said in second flight. Vail said word for aviation center in the air.

GENERAL NEWS

Texans Fly Whirlwind Ryan To 172 Hr. Endurance Mark

Plan to Re-Pilot As Well as Refuel

OAKLAND, (Calif.) — James Wherry, radio operator on the Southern Cross flight, and Harry Abbott, Mills field pilot, plan a refueling mid-air attempt flying in an Avian powered Storm monoplane made in Arnold Industries, Inc., this city.

In addition to refueling, Wherry and Abbott also contemplate changing crews during the flight. The refueling will take place in the morning hours to the place according to their plan, and the pilot going off duty will participate to the ground.

To Offer Whirlwind Plans

FORD DILLON (Calif.)—According to reports from Phoenix, Arizona, concerning reports in which he has been accused by W. W. Webb, of this city, will offer his three plane engine with Whirlwind power following some adaptation from the U.S. model.

New Mark Established Through Refuel Contacts

FORT WORTH (Tex.)—All named flight records were broken last evening afternoon, May 26, when Buzzell C. Hubbard and James Kelly landed their rebuilt Ryan monoplane "Port Worth" at Maclean field to establish an unbroken flight record of 172 hr. 37 min. 1 sec., a mark indicating that the Army's "Quoniam Mark" by more than 21 hr. A flight Whirlwind J-4 engine bearing factory data 6-25-28 powered the miles plane during a long cruise of more than a week.

With the refueling successful, the plane apparently could have kept going the air longer, but a cracked propeller unscheduled fracture the crash to earth. The trouble was started, it is said, when Kelly's belly belt buckle was too tight, caused the blade to hit the main engine. Kelly said the broken arm of the J-4's 30-hp. motor which held the engine against the rock in the blade until it was dangerous to continue with it. Kelly said the engine was broken the Ryan at 4:05 p.m. May 26.

Refueled Ryan Another Run

The first fuel tank off from Maclean field at 11:35 Sunday May 26, carrying some 250 gal. of gasoline. Earl Maclean, a 1928 Ford, was on duty and accompanied in 113 gal. of fuel into a 35 ft. tank from another Ryan. "Whirlwind" data 6-25-28, fuel tank and 11.5 Jones reflecting continued throughout the work in an average of seven days.

The flight was made while in the vicinity of Maclean field here with the company of a period May 28 when an electrical storm threatened and the Ryan flew to Love Field, Dallas, to make check a refuel. Reichenbach claimed that a record flight of the Ryan, the same field from which it starts, broke the late "Stagger" Maclean's order and to suffer through a forced landing, however.

Reichenbach's Q2 and Port Field

The Birmingham place was fixed, as ending in specifications of the Ryan. The road was covered by the Ryan of the cabin to enable refueling. Instruments used were Consolidated Jones Company's Tynes the Ryan Ryan. The Ryan's power instrument Company had said were reliable and safe at (Continued on page 1898)

10,000-mile amazing WARNER-SCARAB performance

ARRIVAL AT NOME, ALASKA, APRIL 23, 1939

One month is the time it took to take the Scarab from New York to Nome, Alaska, via Siberia, and back to New York.

Using the same plane and the same engine (No. 26) with which Earl Rickard won the New York to Los Angeles Air Derby last September and being 1000 miles a day when necessary, Crane made the trip in 114 days, losing only 1000 the slight adjustments in the engine mentioned in the telegram herein mentioned. And the return flight from New York to Nome was made in 46 hours flying time.

During the flight all altitude conditions were maintained, beginning with the almost mid-winter temperature in Russia, the soaring peaks through the tundra, spring air at Alaska and into the cold weather of Alaska and Siberia.

Considered from every viewpoint this most recent Warner-Scarab performance is a magnificent tribute to the power, taking care and skill used in the design and production.

A Touch of the Finger Controls World's Largest Beacon Mounted on **SKF** Bearings

So well as the weight of the world's largest airplane beacon believed that it can be controlled almost with the touch of a finger. This gigantic searchlight known as "The Jefferson Light," and installed atop the Charleston Hotel, Charlottesville, Va., was built by the Sperry Gyroscope Company and is fully equipped with **SKF** Ball Bearings.

For riders of the night are safely guided by

the powerful beam of 1,500,000,000 candles which pierces the sky from this beacon. The reflecting mirror is forty-two inches in diameter. The lamp can be turned 360 degrees in azimuth and its beam can be directed vertically into the air. Unfading dependability, smooth operation and freedom from close attention, these were the things placed above all considerations in the choice of **SKF** Bearings.

NINETY MILES — 11.80

PILOT and passenger in an hour's flight on less than four gallons of fuel—90 miles for \$1.80—two cents a mile. *Astounding—and true* of the Aeromarine Klemm AKL25. Designed originally as a glider—powered by its perfectly adapted Salmson 40-50 horse power, nine-cylinder, radial, air-cooled engine—there are sound reasons back of this astounding economy of operation. Although some planes have to be dragged through the air, the AKL25 literally flies itself . . . reducing resistance to a minimum. Private owners will appreciate this, and for the flying school operator the above cost figures mean an actual saving of 30% over the average of standard competition during instruction flights. Add the plane's maneuverability, ease of control and the ruggedness of sound engineering—and you know why the AKL25 is repeating its European popularity—why in America it has become the favorite light plane for private ownership and the training of pilots. The AKL25 bears the Department of Commerce Approved Type Certificate No. 121.

KREIDER-REISNER

The high performance Fairchild KR 21g, a three place biplane, formerly the Kreider-Reisner "Challenge" C-14.

Off the ground as fast! Faster climbing! Higher speed in the air! This has always been the reputation of Kreider-Reisner planes. General engineering has made them light, with an excess of strength and ruggedness. They are and extensively when fields are small and rough — these performance counts. They are adapted to the service, and need a minimum of repair.

STANDARD equipment on Kreider-Reisner planes includes many instruments and accessories including: headlight, compass, altimeter, compass, barometer, oil pressure gauge, inter-structure gauge and gasoline gauge. Other class of standard equipment include a master starter, dual controls, radio or radio (on the wing-cooled engine), engine starter, engine reverse (on wing-cooled engine only), landing gear, tools, log book, first-aid kit and fire extinguisher.

In addition, the latest engine is also paid for the installation of an oil-pressure gauge and as the case of the KR-21, oil pressure and oil-temperature gauges are installed in the front engine. The wings of the KR-21 and KR-21 are wired for navigation lights. Wheel brakes are standard equipment on the KR-21 and can be had as extra equipment on the KR-21.

Famous for performance Built for SAFETY!

You don't have to be a Lindbergh to judge the exceptional air-worthiness of the Ryan. One inspection tells you that here is no fair weather ship, but a craft engineered to withstand the unexpected stress and strain of dire weather.

You see it in the Ryan's extremely braced wing construction—the strongest known. Its superiority to other types is readily apparent when you consider the heavier pay loads ships must carry today. Furthermore, it permits adjustments to compensate warping, which are impossible in the cantilever type wing.

You see it in the exclusive Ryan designed chassis with rods of Chromolybdenum steel tubing—the landing gear that stood up under the terrific shock of two and one-half tons weight on the take-off of the historic Paris flight. A landing carriage that will stand the gulf when you hit the dirt of the roughest fields.

You will see it, too, in the braces through

the center of the Ryan's cabin. No other ship offers this safeguard to passengers and plane against the rocking strain of rough landings. It adds naturally to the life of the ship. And if the brace were removed, you could see it again in the steel-rigging bracing, motor-welded at the joints and braced against torque and strain by diagonal steel members. Such plus construction characterizes the Ryan from any other ship to render it makes the world's most famous ship the safer, too.

As to performance, the whole world knows what the Ryan can do. Here (see left) are a few details which "Red" Hergan, at the factory, or any Ryan distributor, will gladly demonstrate. Send for new, illustrated catalog of the new Ryan Brighthouse for us, powered by the Wright Whirlwind J-4 engine. CHARGE FOR AVIATION

Building a hangar? Planning an airfield? Facing any airport problem?

A model hangar at Minneapolis in which Robertson materials were used.

Come to ROBERTSON

LET'S not make any unavoidable mistakes. There is so much yet to be done in this aviation industry . . . so many claims upon every penny of available capital . . . that none of us is justified in repeating experiments that have already failed, or in making mistakes that cost money.

Take hangars, for instance. So many things have already been proven about them that there is no need to make costly experiments. There is no use, for example, to take a chance on unprotected metal roofing or siding for hangars. Do what you will, they will rust away.

There is no use, on the other hand, to sink thousands of dollars into "heavy construction." It costs too much, and moreover it is a dead loss if ever you want to make any changes in

your field. For another thing, there is no use ignoring the need for natural daylighting in hangars.

These and hundreds of other problems have been met and solved. The Robertson engineers have participated in all manner of trials and experiments in hangar construction all over the world since before the birth of modern commercial aviation. They know the answers to most of the questions. Let them look over your plans. Their suggestions will cost you nothing and will not obligate you. Just send your blueprints or plans to

CHARGE FOR AVIATION

Here, thee finds an extra quart in every gallon!

THESE may have observed containers of Quaker State Aero Oil, without special curiosity. Yet it will pay thee to investigate their contents.

It is all that it *oil* lubricant—and in this fact differs materially from ordinary oils. For the makers of Quaker State Aero have developed a special process—*super-refining*—an extra step beyond the point where the refiner ordinarily leaves off. By this process there is removed the quart or more of non-lubricating material—of little or no value to the motor—which is present in each gallon of ordinary oil. Thus, in Quaker State Aero there obtains *four* full quarts of lubricant—in truth, *an extra quart*.

Furthermore, Quaker State Aero is refined exclusively from 100% pure Pennsylvania Grade Crude, whose superior quality makes it cost two to three times as much as the crudes from which most oils are refined.

Thus, every drop of Quaker State Aero is the finest lubricant which Man and Nature together have devised for the protection of thy motor. There will find, through one filling of this excellent oil, that these words are not idly spoken. Test their truthfulness in thy next flight!

More than 500 distributing wire houses, and 80,000 dealers, have been established in the United States and Canada, to enable thee to obtain Quaker State Aero on all thy journeys. Profit thereby!

ROBIN PERFORMANCE

▲ ▲ WHAT THEY SAY ABOUT THE ROBIN

FORT WORTH, TEXAS

"Just a note to tell you how delighted we are with our Robins. I came through St. Louis via Muskogee, Oklahoma, Dallas and into Fort Worth in seven hours and twenty minutes, with a head wind the last two hundred and sixty miles. My average speed for this trip was right around sixty-five miles an hour.

I believe the Robin turns up and flies hands off better and with less attention than any airplane I have ever flown. If anybody wants to know about the Robin 'ASK US.'"

(Name on request)

▲ ▲ WHY THEY SAY IT

Superior engineering design alone is responsible for the unmatched Robin performance—the same staff of engineers, that has made Curtiss military planes famous for 19 years, designed the Robin for you.

BASE OF CONTROL AND INSTRUCTION

The Robin maneuver easily. Its structure is part of student instruction at any Curtiss Flying School. In the quiet check valve construction can be used on a second hour making instruction doubly effective.

h.p.—.5. Oil consumption,
cubic inch, pounds per
h.p.—.015.

FREE as the air it commands—poised and sure as the hand it honors—soaring in stage as the head honoree, the Black Eagle soars to supremacy of the skies.

You who have yet to experience the fast, smooth flight of COMMAND-AIRE's flowing lines—who have yet to glory in the tremendous power, compactness, positive control, and sense of easy security in this trim, subtle, graceful ship powered by Axelson—upon indeed have yet to drift at what sound engineering has done convincingly for the advancement of aviation.

For, in this splendid combination of correct plane construction (embracing 10 cardinal points of exclusive development) and

the super-power of Axelson's sturdy 7-cylinder, single, radial, air-cooled engine, COMMAND-AIRE contributes a brilliant new achievement among 3-place open type ships.

To you who judge by specifications, we will furnish an impressive catalogue. But first let the Black Eagle convince you by inspiring flight, with what skilled craft this catalogue has been synchronized into the sweetest ship aloft.

To arrange for a demonstration and secure complete literature and specifications, write either address below.

AXELSON MACHINE CO. COMMAND-AIRE, Inc.
Los Angeles, California Los Angeles, California

Presented with the Axelson 7-cylinder engine, the Black Eagle assumes the ultimate height of performance. The Axelson engine is an epitome of lightest mechanical construction. It carries a weighty name—Axelson—so sure that two become a symbol of economy and fine workmanship.

There's ALWAYS a New FRONTIER

Daniel Boone blazed the trail. When Yadkin Valley ceased to be a frontier, he moved on from the Carolinas . . . to Kentucky, to the Kanawha, and finally to the region that is now Missouri . . . finding out what was there . . . hunting with wilderness and Indians . . . conquering new conditions.

Boone typified the first phase of American pioneer life. But with its passing our frontiers did not pass—they only changed . . . changed from unbroken plains to undiscovered markets . . . from tangled wilderness to unexplored industrial problems. Today's frontiers still have their new horizons of expanding opportunities, advancing standards. But in place of woodcraft the modern pioneer must have business sense . . . and the modern business paper is blazing his trail.

♦ ♦ ♦

McGraw-Hill publications are always pioneering on the frontier of business.

They scout the research laboratories, the experimental stations, the testing grounds, the farthest outposts and the latest councils—wherever tomorrow's changes are being conceived—for news, experience and forecast vital to their readers. McGraw-Hill's staff of editors, field correspondents and marketing counselors are themselves leaders in pioneer business thought.

In all, 26 McGraw-Hill publications serve American engineering, industry, trade and business. Each has its field—chemical engineering, electricity, metallurgy, mining, textiles, construction, transportation, aviation, radio, machinery, food, power, plant management, business administration.

The Magazine of Business serves the policy-forming leaders of American business. Each McGraw-Hill publication carries with it to new frontiers the full resources of the entire McGraw-Hill group.

Aircraft Industry

Enjoys Unique Advantages in Los Angeles County

32% of the aviation activity in the entire United States centers in Southern California. (U. S. Dept. Commerce)

Available investigations by meteorologists, industrial engineers and aviation authorities show conclusively that atmospheric, geographic, industrial and other conditions here are particularly favorable to aviation industry.

12 major factories are now manufacturing airplanes and aircraft motors here. Highest type, experienced, skilled labor is available; 20% of all licensed pilots; 20% of all identified aircraft; 25% of all aviation schools in the United States are in Southern California.

There are 50 or more airports and landing fields in Los Angeles County alone. (See graphic map at left).

Climatic and other conditions are bound to make this the aviation capital of America. The advantages of this immediate territory are not to be had elsewhere.

Complete detailed surveys and information promptly furnished upon request to the Industrial Department.

THANK YOU for working AVIATION

George I. Stapp, well known as the president of the Aero Supply Company, heads the new organization.

ANNOUNCING AN IMPORTANT MERGER

We take pleasure in announcing to the aviation industry the consummation of a merger of the Aero Supply Mfg. Co., Inc., of New York, the Standard Avionics Products Corp'n, of Coney, Penn., and the National Seed Products Co., of Dayton, Ohio. The three plants will hereafter be operated as the Aero Supply Mfg. Co., Inc., with headquarters at its offices—College Point, Long Island, New York. The object of the merger is to give to the industry a hitherto unequalled service in supplies and material, ultimately including everything necessary in the fabrication of airplanes—except motors. The highest possible standards of quality will continue to engage the concentrated and coordinated efforts of the new entity, which has for its creed the well known Aero Supply slogan—"Make it safe for the flyers—the world over."

LIGHTING THE HARBORS

Newark Airport at night as illuminated by an installation of Westinghouse Chromalite Floodlights

DARKNESS, for years the sinister element which has stubbornly fought the progress of aviation, is rapidly being routed. Today thousands of miles of Airways, marked by sweeping beacons, guide the night pilot safely over mountains, lowlands and forests to his destination. At the airport, night has been turned into day.

In this development of aviation lighting, Westinghouse, with years of experience in many classes of illumination, has made important contributions. Westinghouse Chromalite landing field floodlights

illuminate the airport brilliantly, but without the glaring, upward rays which blind the pilot as he levels off for a landing. Multiple lighting units eliminate the danger of lighting failures at a critical moment; while the flexibility of installation permits perfect illumination of surface conditions and allows economical expansion to take care of increased night traffic.

Westinghouse lighting equipment in many airports throughout the country is making night landings as safe as those by day.

TRUCK BOX for handling AVIATION

There's an R-W Way for every doorway

The hangar of the Stewart Aircraft Company at the Cleveland Municipal Airport has a storage capacity of 10 planes. The doorway of the hangar is 56 ft. wide by 13 ft. 9 in. high.

When Richards-Wilcox engineers were called in to solve the doorway problem for this large opening, they installed 6 all-steel doors. They operate on curved rails which permit the doors to slide back to either side, allowing a full width unobstructed opening without crater pits.

The top of the doors are guided by ball-bearing rollers between two channel irons. The whole weight of the doors—approximately 3 tons—is carried on R-W ball-bearing rollers running on four rails freely included in concrete. The ball-bearing rollers give perfect balance to the doors and make one-man operation easy.

The Richards-Wilcox all-steel construction makes a door that will not warp or swell because of rain, snow, and freezing weather.

Richards-Wilcox all-metal doors and door hardware are not just so much hardware and material. Behind every installation are Richards-Wilcox engineers, who design doorway equipment to function efficiently, economically, and without trouble. If you have a doorway problem an R-W doorway engineer will be glad to talk it over with you. There's an R-W Way.

April 26, 1935
Mr. E. W. Smith
Wright, Peabody, Kansas
Wichita, Kan.
Dear Mr. Smith:

Thank you very much for the
information received and the letter
concerning the Peabody, Kansas
flight. I am glad to hear that the
flight was successful and that the
plane has been safely returned.
I am glad to hear that the flight
was successful and that the plane
has been safely returned.

The flight was very successful
and the plane was safely returned.
I am glad to hear that the flight
was successful and that the plane
has been safely returned.

Very truly,
Elmer Smith

26 hours-23 min.-2 qts. of Oil

Elmer Smith's record-breaking endurance flight over Roosevelt Field in her Belcon—Whitwind Cabin Monoplane, on April 23rd and 24th, will be long remembered for the following notable features:

First of all, a plucky 17-year-old girl broke the World's endurance record by 4 hours and 18 minutes.

Secondly, only three other persons—Charles Lindbergh, Martin Jensen and Royal Thomas—have flown solo for more than twenty-four hours.

Thirdly, of the 65 gallons of Kendall Peabody Oil with which the flight started, 8 gallons were remaining at the finish—a total oil consumption of only two quarts.... A truly remarkable indication of the value of good lubrication.

World's records in the air are not achieved easily. Exceptional pilots, exceptional planes,

exceptional engines and wise planning are all necessary. Pilots plan wisely when they select Kendall Oil for difficult lubricating tasks. Kendall Oil insures efficient engine performance plus conservation of gasoline, for a smoothly running, perfectly lubricated motor is able to deliver the last ounce of power of which it is capable.

Only an oil as good as Kendall can be recommended for faultless performance for thirty hours or more without change. And the oil that stands up longest, lubricates best. Throughout Elmer Smith's flight, Kendall Peabody Oil performed as it can always be relied upon to do, according to specification. For a list of airports where Kendall Peabody Oil is now obtainable, address Aviation Division, Kendall Refining Co., Bradford, Pa.

Truly—PERFORMANCE WITH ECONOMY

WEAVE THE ALEXANDER AVIATION

...and Tail Wheels shall set them free

Goodrich Tail Wheels prevent planes from skidding on the ground with almost as much freedom and independent movement as wheels they bear on a automobile.

The Goodrich Para-matic Non-slip Tail Wheel is used on Ford Trimotor Planes.

There are eight different sizes and models of Goodrich Tail Wheels in all. The smaller tail wheels are made of sponge rubber.

FREE . . . to push their new planes out of the hangar . . . unstalled!

Free . . . over their way across hangars, to wade through parked cars and pedestrians . . . and head up into the wind alone.

Free . . . to take all packing, routes. To land safer. With less shock to the fuselage and more comfort for the passengers!

. . . these are only a few of the interesting new thrills made possible by Goodrich Non-slip Airplane Tail Wheels.

There is a more sober significance in their adoption by manufacturers who have adapted them to their own new model airplanes.

The stability of tail-wheel planes opens up a wide market to private ownership. The wheels eliminate the necessity of hanging at airports or public airports.

Goodrich now supplies eight complete new tail wheel unit constructions ready for assembly right on to the plane.

the NEW SERIES SIEMENS

FACTOR ONE: DESIGN

Siemens, giant engineering firm employing over 130,000 skilled workers, in their 17 years' study and research of the requirements of a power plant for aircraft, have produced radial air-cooled engines designed to give maximum power with minimum mass.

At the same time, the essentials of certainty of operation, effective mechanical balance, and uniform delivery of power have been preserved. Minimum consumption of fuel and lubricating oil are additional features of the NEW SERIES SIEMENS.

The NEW SERIES SIEMENS meet and exceed every requirement of the American aircraft builder, retaining, in addition, the features of previous models which are still noted for their

Belden Shielded Aircraft Cable for Planes Equipped with Radio

BELDEN Radio Shielded Cable has been a tremendous aid in the development of radio communication in aircraft service.

Nearly every American plane that has achieved great success has been equipped with Belden Wire on its radio service. A few of these famous planes are shown in the illustrations.

The use of Belden Aircraft Wire and Cables year in and year out by leading airplane manufacturers and on planes of outstanding achievement is significant evidence of their high quality and their dependability. It will pay every aircraft manufacturer and every aircraft operator to visit the Belden Aircraft Wire Cables.

Long Island City, New York

A VAST TESTING LABORATORY *that points to one conclusion!*

THE air mail service—flying a daily average of 38,000 miles—is the vast testing ground of aviation, where theories and materials for their baptism of fire—where their weaknesses are found out—their strengths developed.

From this testing laboratory has come the inescapable conclusion: Aluminum and its alloys are sure to play a part of ever-increasing importance in the development of aviation.

Already more than one half the material in the modern airplane engine is Aluminum alloy, with a weight saving of more than 50% over iron or steel.

Forged Aluminum alloy propellers with an almost everlasting life have dis-

placed easily shattered wood with its average life of less than 200 flying hours.

And there is hardly a part of the fuselage to which designers are not applying Aluminum alloys with a consequent gain of strength, durability and safety.

Aluminum Company of America offers a dependable supply of Alclad sheet and tubes, and of castings, forgings and screw machine parts, made of Aluminum and its alloys. Inquiry, correspondence and personal contact with our technical staff is invited.

Steel Serves Best—for Less

DATA
FREE

Our Engineering Department will furnish you complete data on your proposed Hangar. Write for it, specifying number of ships and makes.

Why not place your most valuable ship in a building that is absolutely fire, lightning and weather proof?

ESLINE HANGARS give greatest protection, are most economical to maintain, and give you every advantage in design, construction and at the lowest price obtainable.

ESLINE HANGARS come ready to erect—saving much time and labor costs. Practically no depreciation after years of service. 100% salvageable.

BUY—
DON'T BUILD—Patented and
Fire Proofing"HALLOWELL"
STEEL WORK-BENCH

We make "HALLOWELL" Steel Work-Benches and Tables in 1368 different sizes and combinations and carry them in stock for immediate shipment so we are sure to have just what you want—when you want it.

The "HALLOWELL" Steel Bench and Table Tops are smooth and serviceable; they never splinter, crack or get oil soaked; are easy to keep decently clean and will last a lifetime—so different from wood.

Besides, "HALLOWELL" Steel Equipment is rigid, rugged, fireproof and inexpensive in the bargain.

We also make "HALLOWELL" Steel Bench Drawers—carry them in stock, and sell a lot of them.

By now, no doubt, you are thoroughly interested and therefore please write our Johnny Martin and ask for

A thoroughly revised second edition of

Physics of the Air

By W. J. MUMPHREY

A non-mathematical, practical, and modern treatment of the subject

454 pages, 6x9, 224 illustrations, \$4.00

This book is a new edition of the first edition, which was published in 1928. It is a revised and enlarged edition, with many new illustrations and a new chapter on the physics of the air. The book is written in a clear and concise style, and is suitable for use as a textbook or a reference work.

The author has a long experience in the field of aerodynamics, and has written many books on the subject. This book is a revised and enlarged edition of the first edition, which was published in 1928. It is a revised and enlarged edition, with many new illustrations and a new chapter on the physics of the air.

The book is written in a clear and concise style, and is suitable for use as a textbook or a reference work. It is a revised and enlarged edition of the first edition, which was published in 1928.

AIRPLANES

TO THE GROWTH OF AIRPORTS

THE number of excellent flying fields in America is increasing so rapidly that even in listing them the Department of Commerce has difficulty. Something of the same sort is true of Wright engines. The average man thinks automatically of Wright when he thinks about

aviation. The public knows that it was in a Wright-powered plane that Lindbergh made his memorable visit to Paris and it is with Wright engines that most of the famous trans-oceanic flights have been made.

Wright engines . . . and modern, conveniently located airports . . . have done as much as any other factors to build up confidence in flying.

Statistics show that approximately thirty-five per cent of all the airplanes in America are powered by Wright. This, of course, is most impressive proof of Wright efficiency and safety.

Ninety-four per cent of the parts for "Whirlwind" motors are interchangeable. And the twelve regional distributors listed in this advertisement carry as complete a stock of Wright parts as can be found at our factory. Under these distributors a large and growing number of Approved Service Stations function. They network the whole country, and as new airports are established, new Wright Service Stations come into existence.

The list of Wright distributors is printed here to make it easy for flyers, owning Wright-powered planes, to know where spare parts can be quickly obtained.
